

Do higher property values increase fire suppression costs?

Connor Lennon

Fall 2021

Over the last ten years, the US spent **\$21.4** billion on fire suppression

Most recent data (1990-2010) shows rising numbers of **WUI** homes

[2] What is **causing** these higher costs?

What causes fires to be **more** or **less** expensive to suppress in the first place?

Major policy concern: association between **property values** and **expense of fire suppression** (observed by existing literature) → **regressive!**

Is this association due to a bias towards protecting wealth directly or due to expensive homes being built in places that are expensive to fight fires?

Potential Fire Paths
Effect on suppression expenditure

Complication: Dynamic expectations.

Which paths a fire could take impact expected costs. Suppression decisions impact actual paths AND costs.

Expected paths affect suppression decisions, homes at risk, and costs.

Simultaneity problem arises if statistically analyzed ex-post, but disappears if examined using ex-ante data.

[3] Outline

Research goal: Decompose the fire manager's problem to identify:

H₁ Do fire managers preferentially assign more resources to fires near expensive properties?

H₂ How much of this correlation between fire suppression and property values is due to physical attributes common to expensive properties and higher suppression costs?

Note: Could be both!

Methods: Double/Debiased Machine Learning

- Uses **C**ompact **C**onvolution **T**ransformer (**CCT**), to model nonlinear confounders in a regression model (e.g., Slope, Fuels, Canopy Cover, Accessibility ...)
- Produces causal estimates of property value on fire suppression costs, controlling for machine-learned fire risk attributes

[4] Causal System

Research Question

P.V.: Property Values | **Supp**: Suppression Costs

[4] Causal System

Basic Hedonics

P.V: Property Values | **Supp**: Suppression Costs | **Envir**: Environment | **Amnty**: Amenities |
FireRisk : Fire Risk | **Ex.Supp**: Expected Suppression Costs

[4] Causal System

Basic Physics

P.V.: Property Values | **Supp**: Suppression Costs | **Envir**: Environment | **Amnty**: Amenities |
FireRsk : Fire Risk | **Ex.Supp**: Expected Suppression Costs

[4] Causal System

Fire Manager's Expectation/Information

P.V.: Property Values | **Supp**: Suppression Costs | **Envir**: Environment | **Amnty**: Amenities |
FireRisk : Fire Risk | **Ex.Supp**: Expected Suppression Costs

✓ **GOAL:** Disentangle the physical components of expected fire suppression costs from the human/bias-driven tendency to protect expensive property. Use models of fire spread and values at risk to embed expected suppression into pathways.

We need an algorithm that can simultaneously combine short-and-long-distance dependencies of amenities on elevation, fuels, water-features, telephone, etc. **Enter Vision Transformer CCT.**

D/DML uses out-of-sample estimates from a vision transformer to estimate the causal effect of property value on suppression, controlling for flexible associations between fire-level per-acre Suppression Expenditure and Environment, Amenities and Fire Risk across two control functions $\eta = \{f(x), g(x)\}$ which represent the nonlinear affect of control variables x on fire suppression costs and housing prices respectively

Estimates based on **fire ignition point data** (the current ex-ante approach) fails to capture some important variation in fuels, elevation and amenities that may bias estimates of θ .

So far: my estimates point towards a significantly smaller effect from property values on suppression costs than existing literature - I find, for a **1% increase in property values**, suppression costs **increase by .038%**, which compares to a **reported .11%** increase from Gebert et al. 2007 and **a .16% increase** when replicating Gebert et al. on data from 2020-2021. This difference is statistically significant.

[6] Work to do

Presentations - need to work on this. In particular, would like to work on getting a tight 10 minute talk as well as a 20 minute version. Plan to present at economic micro group and metrics group

Drafts - an early draft done by mid November. I hope to circulate this draft to my committee, and have offers to get feedback from Matthew Wibbenmeyer and Margaret Walls. Depending on feedback, third draft, followed by final draft.

Defended April 1st, 2022.

Need to run full model on all 10 folds* (as of now, only applied to one fold, but results have small confidence band, and more iterations should reduce the size of this band)

Potentially repeat procedure for building-assigned income by tract? If of interest.

Likely useful to do some degree of ablation tests for my version of CCT. Others?

*:X Folds: Dataset split into fractions of $1/X$, use $X-1/X$ to train, $1/X$ to predict out of sample
